TITLE OF THE INVENTION

Virus purification methods

FIELD OF THE INVENTION

5 The invention belongs to the field of purification of virus, more in particular recombinant adenovirus, from host cells.

BACKGROUND OF THE INVENTION

Viruses, either those occurring in nature, or recombinant 10 versions thereof, are used for vaccination and in the field of gene therapy. It is possible for many viruses or virus-like particles to safely and efficiently propagate these in host cells (see for instance WO 01/38362, which describes the propagation of various viruses in host cells being E1-immortalized retina cells). Recombinant adenoviruses are a 15 preferred class of viral vectors for use in gene therapy and for vaccination purposes. Such recombinant adenoviruses are usually deficient in at least the E1 region, and are propagated in complementing cells providing the E1-region, 20 such as 293 cells, or E1-immortalized retina cells such as PER.C6™ cells (see for instance US patent 5,994,128).

After propagation of the viruses in the host cells, for virtually all applications it is necessary to purify the viruses from the host cells, before further use.

25 International patent application WO 98/22588 describes methods for the production and purification of adenoviral vectors. The methods comprise growing host cells, infecting the host cells with adenovirus, harvesting and lysing the host cells, concentrating the crude lysate, exchanging the buffer 30 of the crude lysate, treating the lysate with nuclease, and further purifying the virus using chromatography.

Several other publications describe the purification of viruses from host cells, mostly concentrating on the use of specific chromatographic matrices for purification of the virus from a host cell lysate, see e.g. US patents 6,008,036, 5 6,586,226, 5,837,520, 6,261,823, 6,537,793, and international patent applications WO 00/50573, WO 02/44348 and WO 03/078592.

Most of the described methods apply a nuclease treatment step to degrade DNA impurities. Despite the description of several processes regarding different chromatography matrices, 10 a need remains for alternative and preferably improved methods for virus purification from host cell cultures. The present invention provides such methods.

DESCRIPTION OF THE FIGURES

15 Fig. 1. Scheme of the known method of harvesting the cells (T/B) versus the method according to the invention (B/T), see example 1. T: Triton, B: Benzonase. p.i.: post infection.

Fig. 2. Host cell protein removal at clarification after T/B 20 vs. B/T process (see Fig. 1 for scheme). A silver-stained SDS-PAGE (4-12% bis-tris NuPAGE, Invitrogen) analysis of in process samples of 5 separate purifications is shown (see example 1 and Table 1 for samples). Panel 2 is from a T/B harvest, wherein lysis preceded nuclease addition; panels 3-7 25 are from a B/T harvest, wherein nuclease was added before lysis. The harvest (lanes 1) was clarified by a 0.5 μ m Clarigard filter (lanes 2), followed by a 0.8/0.45 μ m Sartopore 2 filter (lanes 3). M: marker, M_w in kD is shown alongside.

30 Fig. 3. Diafiltration with high salt removes histones during process (see example 2). A silver-stained SDS-PAGE is shown.

A. Permeate. Samples: 1: initial permeate. 2: after 4x concentration. 3: 1st DFV 0.3 M NaCl. 4: 3rd DFV 0.6 M NaCl. 5: 4th DFV 0.6 M NaCl. 6: 5th DFV 1.0 M NaCl. 7: 6th DFV 1.0 M NaCl. 8: 7th DFV 0.3 M NaCl. 9: 9th DFV 0.3 M NaCl. M: marker, 5 M_w in kD is shown alongside.

B. Retentate. Samples: 1: start sample. 2: after 4x concentration. 3: 1st DFV 0.3 M NaCl. 4: 2nd DFV 0.6 M NaCl. 5: 6th DFV 0.6 M NaCl. 6: 7th DFV 1.0 M NaCl. 7: 8th DFV 1.0 M NaCl. 8: 9th DFV 0.3 M NaCl. 9: 9th DFV millex (0.22 μ m filtrate 10 of sample 8). M: marker, M_w in kD is shown alongside.

Fig. 4. Scheme of a preferred process according to the invention (see example 1).

15 Fig. 5. Removal of Ebola nucleoprotein (NP) from recombinant virus preparations (see example 3, experiment 3.1 for details). A silver-stained SDS-PAGE (4-12% bis-tris NuPAGE, Invitrogen) is shown. A: starting material. B: incubation with 1% Tween 20. C: incubation with 2.5 M NaCl. The arrow denotes 20 NP.

Fig. 6. Experiment for removal of Ebola nucleoprotein from recombinant virus preparations (see example 3, experiment 3.3 for details).

25 Fig. 7. Non-reduced SDS-PAGE (panel 1) and Western blot (panel 2) analysis of removal of Ebola nucleoprotein (NP) from recombinant virus preparations (see example 3, experiment 3.3 for details). Lanes A, B, C contain product A, B and C, 30 respectively (see Fig. 6 and experiment 3.3). For the Western blot analysis, an antibody recognizing NP was used. The arrows denote NP.

Fig. 8. RP-HPLC analysis of removal of Ebola nucleoprotein (NP) from recombinant virus. Products A, B and C were analysed. For details see example 3, experiment 3.3. The vertical axis are in AU ($\times 10^{-3}$). Under the horizontal axis (elution time), arrow 1 indicates the peak of hexon protein, arrow 2 indicates peak of NP.

Fig. 9. SDS-PAGE (panel A) and Western blot (panel B) showing the removal of of Ebola nucleoprotein (NP) from recombinant virus preparations using high salt and filtration. After anion exchange chromatography the sample was buffer exchanged with a solution comprising 5M NaCl. The sample was directly filtered through a 0.45 μ m Millipac 20 filter (Millipore). Lane 1: before filtration, lane 2: after filtration. For the Western blot, an antibody recognizing NP was used. The arrow denotes NP.

DESCRIPTION OF THE INVENTION

The present invention provides a method for the purification of a virus from a host cell, said method comprising the steps of: a) culturing host cells that are infected with a virus, b) adding nuclease to the cell culture, and c) lysing said host cells to provide a lysate comprising the virus. In preferred embodiments, the method further comprises: d) clarification of the lysate. In still more preferred embodiments, the method further comprises: e) further purifying the adenovirus, preferably with at least one chromatography step. The most important difference with the methods hitherto disclosed, is that in those methods a nuclease is applied only after lysing the cells, or at a later stage in the purification process. According to the present invention, a nuclease is added before

lysing the cells. As disclosed herein, it has now been unexpectedly found that this results in an improvement over the processes wherein nuclease is added only after the cells have been lysed. In the method according to the present invention, the purified virus batch resulting from this process contains less host cell DNA than with the method wherein the lysing of cells precedes the nuclease addition. In a preferred embodiment, the virus is a recombinant adenovirus. In one embodiment, the nuclease used in step b) is benzonase®. In one embodiment, the step of lysing the host cells (step c) is performed with a detergent, which in one embodiment thereof is Triton-X100. In one embodiment, the clarification of the lysate (step d) comprises depth filtration and membrane filtration. In a preferred embodiment thereof, said membrane filtration is performed using a combination of filters having a pore size of 0.8 μm and 0.45 μm , such as a combination filter comprising two asymmetric polyethersulfone membranes with pore sizes of 0.8 and 0.45 μm , such as a Sartopore™-2 combination filter. In one embodiment, the clarified lysate (resulting from step d) is subjected to ultrafiltration and/or diafiltration. In a preferred embodiment thereof, the diafiltration results in buffer exchange against a solution comprising 0.8-2.0 M NaCl, or another salt providing an equivalent ionic strength. In certain preferred embodiments, further purification of the virus (step e) comprises anion exchange chromatography. In another embodiment, said further purification of the virus (step e) comprises a size exclusion chromatography step, preferably in group separation mode. In another preferred embodiment, step e) comprises both anion exchange chromatography and size exclusion chromatography. In certain embodiments according to the invention, the clarified lysate and further purified virus (from step d onwards) are in

buffers that are free of detergent, magnesiumchloride and sucrose.

In another aspect, the invention provides a batch of recombinant adenovirus comprising a transgene chosen from the 5 group consisting of: an Ebolavirus nucleoprotein, an Ebolavirus glycoprotein, a Plasmodium falciparum circumsporozoite gene, and measles virus hemagglutinin, said batch characterized in that it contains less than 0.1 ng host cell DNA per 1E11 viral particles.

10 The invention further provides a method for the production of a virus comprising a nucleic acid sequence coding for a nucleic acid binding protein, comprising the steps of: a) culturing host cells that have been infected with virus, b) subjecting said culture of host cells and said virus 15 therein produced to lysis of the host cells to provide a lysate comprising said virus, c) subjecting the virus to anion exchange chromatography, characterized in that after anion exchange chromatography the virus containing mixture is buffer exchanged with a solution comprising at least 1 M NaCl, or 20 another salt providing an equivalent ionic strength.

Preferably, said solution comprises at least 1.5 M NaCl, more preferably at least 2 M NaCl, still more preferably at least 3 M NaCl, still more preferably about 5 M NaCl, or another salt providing an equivalent ionic strength. Preferably said virus 25 is further purified using filtration through a hydrophilic filter, preferably with a pore size not larger than 1.2 μm , and/or by size exclusion chromatography. The virus preferably is a recombinant virus, more preferably a recombinant adenovirus. The nucleic acid binding protein may be a nuclear 30 protein, such as a nucleoprotein of a haemorrhagic fever virus, such as Ebola, Marburg or Lassa virus, preferably Ebola virus.

DETAILED DESCRIPTION OF THE INVENTION*Host cells*

A host cell according to the present invention can be any host cell wherein a desired virus can be propagated. For example, 5 the propagation of recombinant adenovirus vectors is done in host cells that complement deficiencies in the adenovirus. Such host cells preferably have in their genome at least an adenovirus E1 sequence, and thereby are capable of 10 complementing recombinant adenoviruses with a deletion in the E1 region. Further the adenovirus may have a deletion in the E3 region, which is dispensable from the Ad genome, and hence such a deletion does not have to be complemented. Any E1- 15 complementing host cell can be used, such as human retina cells immortalized by E1, e.g. 911 (see US patent 5,994,128), E1-transformed amniocytes (See EP patent 1230354), E1- transformed A549 cells (see e.g. WO 98/39411, US patent 5,891,690), GH329:HeLa (Gao et al, 2000, Human Gene Therapy 11: 213-219), 293, and the like. Preferably PER.C6TM cells (US 20 patent 5,994,128), or cells derived therefrom are used as host cells, as they are suitable for the propagation of various 25 different viruses (see e.g. WO 01/38362), including but not limited to recombinant adenoviruses.

Further cell lines and methods for the propagation of recombinant adenoviral vectors have for instance been 25 disclosed in US patent 6,492,169 and in WO 03/104467.

Examples of other useful mammalian cell lines that may be used directly as host cells for propagating viruses or converted into complementing host cells for replication 30 deficient virus are Vero and HeLa cells and cell lines of Chinese hamster ovary, W138, BHK, COS-7, HepG2, 3T3, RIN and MDCK cells, as known to the person skilled in the art.

Host cells according to the invention are cultured to increase cell and virus numbers and/or virus titers. Culturing a cell is done to enable it to metabolize, and/or grow and/or divide and/or produce virus of interest according to the 5 invention. This can be accomplished by methods as such well known to persons skilled in the art, and includes but is not limited to providing nutrients for the cell, for instance in the appropriate culture media. The methods may comprise growth adhering to surfaces, growth in suspension, or combinations 10 thereof. Culturing can be done for instance in dishes, roller bottles or in bioreactors, using batch, fed-batch, continuous systems, hollow fiber, and the like. In order to achieve large scale (continuous) production of virus through cell culture it is preferred in the art to have cells capable of growing in 15 suspension, and it is preferred to have cells capable of being cultured in the absence of animal- or human-derived serum or animal- or human-derived serum components. Suitable conditions for culturing cells are known (see e.g. *Tissue Culture*, Academic Press, Kruse and Paterson, editors (1973), and R.I. 20 *Freshney, Culture of animal cells: A manual of basic technique*, fourth edition (Wiley-Liss Inc., 2000, ISBN 0-471-34889-9)).

The present invention comprises subjecting cultured host cells that are infected with virus to lysis. Culturing host 25 cells and infecting them with a virus is well known to the person skilled in the art. Infecting of host cells can for instance simply be accomplished by exposing the virus to the appropriate host cell under physiological conditions, permitting uptake of the virus. For certain viruses it is not 30 even necessary to start with virus *per se*, as nucleic acid sequences may be used to reconstitute the virus in the cultured cells.

Several aspects of and systems suitable for culturing host cells for adenovirus production can also be found in WO 98/22588, p. 11-28. Methods for culturing cells and propagating viruses in host cells have also been disclosed in, 5 for example, US patents 6,168,944, 5,994,134, 6,342,384, 6,168,941, 5,948,410, 5,840,565, 5,789,390, 6,309,650, 6,146,873 and international patent applications WO 01/38362, WO 01/77304 and WO 03/084479.

10 *Viruses*

The methods of the instant invention are amenable to a wide range of viruses, including but not limited to adenoviruses, pox viruses, iridoviruses, herpes viruses, papovaviruses, paramyxoviruses, orthomyxoviruses (such as influenza), 15 retroviruses, adeno-associated virus, vaccinia virus, rotaviruses, etc.; adenoviruses being particularly preferred. The viruses are preferably recombinant viruses, but can include clinical isolates, attenuated vaccine strains, and so on. In certain embodiments, the present invention is used for 20 concentrating recombinant viruses, preferably adenoviruses, carrying a heterologous transgene for use in gene therapy or for vaccination purposes. For purposes of illustration only, the invention will be described in more detail for recombinant adenovirus, but is in no way limited thereto.

25

Adenoviruses

30 Preferably, the adenoviral vector is deficient in at least one essential gene function of the E1 region, e.g., the E1a region and/or the E1b region, of the adenoviral genome that is required for viral replication. In certain embodiments, the vector is deficient in at least one essential gene function of the E1 region and at least part of the nonessential E3 region

(e.g., an Xba I deletion of the E3 region). The adenoviral vector can be "multiply deficient," meaning that the adenoviral vector is deficient in one or more essential gene functions in each of two or more regions of the adenoviral genome. For example, the aforementioned E1-deficient or E1-, 5 E3-deficient adenoviral vectors can be further deficient in at least one essential gene of the E4 region and/or at least one essential gene of the E2 region (e.g., the E2A region and/or E2B region). Adenoviral vectors deleted of the entire E4 region can elicit lower host immune responses. Examples of suitable adenoviral vectors include adenoviral vectors that lack (a) all or part of the E1 region and all or part of the E2 region, (b) all or part of the E1 region, all or part of the E2 region, and all or part of the E3 region, (c) all or 10 part of the E1 region, all or part of the E2 region, all or part of the E3 region, and all or part of the E4 region, (d) at least part of the E1a region, at least part of the E1b region, at least part of the E2a region, and at least part of the E3 region, (e) at least part of the E1 region, at least 15 part of the E3 region, and at least part of the E4 region, and (f) all essential adenoviral gene products (e.g., adenoviral amplicons comprising ITRs and the packaging signal only). In case of deletions of essential regions from the adenovirus genome, the functions encoded by these regions have to be provided in trans, preferably by the host cell, i.e. when 20 parts or whole of E1, E2 and/or E4 regions are deleted from the adenovirus, these have to be present in the host cell, for instance integrated in the genome, or in the form of so-called helper adenovirus or helper plasmids.

25 The replication-deficient adenoviral vector can be generated by using any species, strain, subtype, or mixture of species, strains, or subtypes, of an adenovirus or a chimeric

adenovirus as the source of vector DNA (see for instance WO 96/26281, WO 00/03029), which for instance may provide the adenoviral vector with the capability of infecting certain desired cell types. The adenoviral vector can be any 5 adenoviral vector capable of growth in a cell, which is in some significant part (although not necessarily substantially) derived from or based upon the genome of an adenovirus. The adenoviral vector may comprise an adenoviral genome of a wild-type adenovirus of group C, especially of serotype 5 (i.e., 10 Ad5) or Ad2. The adenoviral vector may also comprise an adenoviral genome or at least a fiber protein derived from an adenovirus of group B, for instance Ad11, Ad35, Ad51, etc. (see e.g. WO 00/70071), which embodiments have the advantage that less neutralizing antibodies against these serotypes are 15 encountered in the population, and confer the possibility of targeting other cell types, since the tropism of these adenoviral vectors differs from those derived from Ad5. Of course, the person skilled in the art will know that also any other serotype can be applied. The person skilled in the art 20 will be aware of the possibilities to propagate adenoviral vectors of different serotypes on specific host cells, using methods such as for instance disclosed in US patent 6,492,169 or in WO 03/104467, and references therein. Adenoviral vectors, methods for construction thereof and methods for 25 propagating thereof, are well known in the art and are described in, for example, U.S. Pat. Nos. 5,559,099, 5,837,511, 5,846,782, 5,851,806, 5,994,106, 5,994,128, 5,965,541, 5,981,225, 6,040,174, 6,020,191, and 6,113,913, and Thomas Shenk, "Adenoviridae and their Replication", M. S. 30 Horwitz, "Adenoviruses", Chapters 67 and 68, respectively, in Virology, B. N. Fields et al., eds., 3d ed., Raven Press, Ltd., New York (1996), and other references mentioned herein.

The construction of adenoviral vectors is well understood in the art and involves the use of standard molecular biological techniques, such as those described in, for example, Sambrook et al., *Molecular Cloning, a Laboratory Manual*, 2d ed., Cold Spring Harbor Press, Cold Spring Harbor, N.Y. (1989), Watson et al., *Recombinant DNA*, 2d ed., Scientific American Books (1992), and Ausubel et al., *Current Protocols in Molecular Biology*, Wiley Interscience Publishers, NY (1995), and other references mentioned herein.

10

Transgenes

In one embodiment, the virus according to the invention is a wild type virus, or a mutant or part thereof that is still infectious in host cells according to the invention.

15 In another embodiment, the virus is a recombinant virus comprising heterologous information, which may be used in a therapeutic setting for gene therapy purposes, or as an antigen for vaccination purposes. This is a preferred embodiment using for instance adenoviral vectors. The 20 heterologous information is referred to as 'transgene'. The methods according to the present invention are applicable with a virus, preferably adenovirus, comprising any transgene, and hence the nature of the transgene is in itself not material to the present invention.

25 Several possible transgenes have for instance been described in WO 98/22588, p. 42-49. Transgenes that may be present in a virus according to the invention may for instance be therapeutic genes, such as tumor suppressor genes, including but not limited to p53, p16, APC, DCC, NF-1, WT-1, p21, BRCA1, 30 BRCA2, and the like; enzymes, such as cytosine deaminase, HGPRT, glucocerebrosidase, HSV thymidine kinase or human thymidine kinase, etc; hormones, such as growth hormone,

prolactin, erythropoietin, chorionic gonadotropin, thyroid-stimulating hormone, leptin, ACTH, angiotensin, insulin, glucagon, somatostatin, calcitonin, vasopressin, and the like; interleukins and cytokines, such as IL-1, IL-3, IL-12, G-CSF, 5 GM-CSF, TNF, and the like; replacement genes lacking or mutated in specific disorders, such as ADA, factor IX, CFTR, etc; other therapeutic genes such as angiogenesis inhibitors, cell cycle inhibitors and the like; antisense constructs to inhibit expression of for instance oncogenes, such as ras, 10 myc, jun, bcl, abl, and the like; as well as antigens for vaccines such as viral antigens, for instance derived from a picornavirus, coronavirus, togavirus, flavivirus, rhabdovirus, paramyxovirus, orthomyxovirus, poxvirus, hepadnavirus, reovirus, retrovirus, herpesvirus, and the like, for instance 15 more specifically antigens from influenza (with as potential antigens for instance HA and/or NA), hepatitis B (with as potential antigen hepatitis B surface antigen), West Nile Virus, rabies, SARS-CoV, herpes simplex virus 1 and 2, measles, small pox, polio, HIV (with antigens e.g. HIV-1 derived gag, env, nef, or modifications thereof including 20 codon optimized versions, see for instance WO 02/22080), Ebola, Marburg, Lassa virus; or bacterial antigens, fungal antigens, parasitic (including trypanosomes, tapeworms, roundworms, helminths, malaria, etc) antigens, and the like. 25 Clearly, the person skilled in the art will choose the gene of interest that is useful in the envisaged therapeutic setting, be it in gene therapy and/or in vaccination, and is not confined to the list above. It is also clear that control regions for the transgene are preferably present in recombinant viral vectors aimed at expression of the 30 transgene, for instance including a promoter and a polyadenylation signal. These are all aspects well known to

the person skilled in the art, and need not further be elaborated here. Several control regions are discussed in WO 98/22588, p. 49-55.

Some adenoviruses used in the present invention are further 5 discussed in the examples.

Lysing host cells

After infection of an adenovirus, the virus replicates inside the cell and is thereby amplified. Adenovirus infection 10 results finally in the lysis of the cells being infected. The lytic characteristics of adenovirus therefore permits two different modes of virus production. The first mode is harvesting virus prior to cell lysis, employing external factors to lyse the cells. The second mode is harvesting virus 15 supernatant after (almost) complete cell lysis by the produced virus (see e.g. US patent 6,485,958, describing the harvesting of adenovirus without lysis of the host cells by an external factor). For the latter mode, longer incubation times are required in order to achieve complete cell lysis, and hence 20 high yields of virus. Furthermore, the gradual spill of the host cell contents into the medium may be detrimental to the integrity and yield of the obtained viruses. Hence, it is preferred to employ external factors to actively lyse the cells, according to the invention.

25 Methods that can be used for active cell lysis are known to the person skilled in the art, and have for instance been discussed in WO 98/22588, p. 28-35. Useful methods in this respect are for example, freeze-thaw, solid shear, hypertonic and/or hypotonic lysis, liquid shear, sonication, high 30 pressure extrusion, detergent lysis, combinations of the above, and the like. In one embodiment of the invention, the cells are lysed using at least one detergent. Use of a

detergent for lysis has the advantage that it is an easy method, and that it is easily scalable. In another embodiment, the cells are lysed by shear using hollow fiber ultrafiltration, such as described in WO 03/084479.

5

Detergents

Detergents that can be used according to the present invention, and the way they are employed, are generally known to the person skilled in the art. Several examples are for 10 instance discussed in WO 98/22588, p. 29-33.

Detergents, as used herein, can include anionic, cationic, zwitterionic, and nonionic detergents. Exemplary detergents include but are not limited to taurocholate, deoxycholate, taurodeoxycholate, cetylpyridium, benzalkonium chloride, 15 ZWITTERGENT-3-14®, CHAPS (3- [3-Cholamidopropyl] dimethylammoniol]-1-propanesulfonate hydrate, Aldrich), Big CHAP, Deoxy Big CHAP, Triton X-100®, Triton X-114®, C12E8, Octyl-B-D-Glucopyranoside, PLURONIC-F68®, TWEEN-20®, TWEEN-80® (CALBIOCHEM® Biochemicals), Thesit®, NP-40®, Brij-58®, octyl 20 glucoside, and the like. It is clear to the person skilled in the art that the concentration of the detergent may be varied, for instance within the range of about 0.1%-5% (w/w). In certain embodiments the detergent is present in the lysis solution at a concentration of about 1% (w/w). In some pilot 25 experiments of the inventors, use of Triton resulted in less viscous solutions than some other detergents tested (Tween 20, Tween 80, deoxycholate). In one embodiment of the present invention, the detergent used is Triton X-100.

30 *Nuclease*

The present invention employs nuclease to remove contaminating, i.e. mostly host cell, nucleic acids. Exemplary

nucleases suitable for use in the present invention include Benzonase®, Pulmozyme®, or any other DNase and/or RNase commonly used withing the art. In preferred embodiments of the invention, the nuclease is Benzonase®, which rapidly hydrolyzes 5 nucleic acids by hydrolyzing internal phosphodiester bonds between specific nucleotides, thereby reducing the viscosity of the cell lysate. Benzonase® can be commercially obtained from Merck KGaA (code W214950).

10 The concentration in which the nuclease is employed is preferably within the range of 1-100 units/ml.

According to the invention, the nuclease is employed before the cells are lysed. It may be added just seconds prior to (or virtually concomitant with) the lysis step, but 15 preferably the nuclease is added to the culture at least one minute before the lysis step. The cell culture with the added nuclease can then be incubated above process temperature, e.g. around 40°C, or at the culturing temperature (e.g. between about 35°C to about 37°C), or at room temperature (around 20°C) or lower (e.g. around 0°C), wherein in general longer 20 incubation times are required at lower temperature to achieve the same result (see Benzonase® brochure Merck KGaA code W 214950). As a non-limiting example, the incubation can for instance be performed at about 37°C, for about 10 minutes, after which the cells are lysed. Obviously, the nuclease can 25 and preferably will still actively degrade nucleic acid after the lysis step, and in certain embodiments according to the present invention the incubation of the cells with endonuclease after lysis is prolonged for about 50 minutes (resulting in a total time of the nuclease treatment of about 30 1 hour, although this time may effectively be still longer, because it is anticipated that the nuclease will still be functional until it is removed in subsequent purification

steps). This is considerably shorter than the overnight incubation disclosed in WO 98/22588. Of course, longer incubation, such as for instance 2 hours or overnight or longer incubation (in Benzonase® brochure Merck KGaA code W 5 214950, data for up to 30 hours incubation are provided) is also possible according to the methods of the present invention, but is not required to obtain acceptable results. It will be clear that the 'lysis step' (i.e. subjecting the cells containing the virus produced therein to lysis) as used 10 in these embodiments, is meant to be a lysis step employing external factors (see under 'lysing host cells' above), such as a detergent. Obviously, during the culturing of the cells wherein the adenovirus is propagated, some cells may already 15 lyse because of the virus in absence of any external lysis factors. Hence, in preferred embodiments, such lysis in the absence of external factors has occurred in less than 50%, preferably less than 40%, more preferably less than 30%, still more preferably less than 20% of the host cells, when nuclease treatment is started, i.e. preferably nuclease is added when 20 the cells have a viability of at least 50%, 60%, 70%, 80%, respectively.

Although not preferred (see above), methods that are dependent on lysis of the host cells in the absence of external factors can be used. Processes involving 25 'spontaneous' lysis have been described, wherein the use of Benzonase is discouraged (see US patent 6,485,958). However, according to the present inventors it will be beneficial also in such systems to add nuclease during the later stages of the culture, i.e. preferably when the host cells wherein the virus 30 is propagated still have a viability of at least 5%, more preferably at least 10%, still more preferably at least 20% (i.e. when less than 95%, 90%, 80% of the cells are lysed,

respectively). It is anticipated that this will improve the process in quality of the obtained virus when this step would be employed. It is therefore another aspect of the invention to provide a method for the purification of a virus that is capable of lysing host cells from host cells, said method comprising the steps of: a) culturing host cells comprising a virus capable of lysing said host cells, b) harvesting virus following their release into culture fluid without lysis of the host cells by an external factor, characterized in that a nuclease is added to the culture before 95% of the host cells has been lysed. In certain embodiments, the nuclease is added to the culture before 90%, preferably 80% of the host cells has been lysed. The finding of the optimal moment (i.e. corresponding to the optimal percentage of cells that has been lysed) to add the nuclease in these aspects of the invention will depend on the amount of nuclease added and the decrease in specific activity of the nuclease during incubation, and can be empirically found by the person skilled in the art, now the advantage of the addition of nuclease to the culture per se has been disclosed by the present inventors. Clearly, the obtained lysate according to this aspect of the invention can be further purified employing methods and steps as discussed herein, such as filtration and chromatography.

International patent application WO 03/097797 describes alternative methods for purifying adenovirus particles from cell lysates, comprising the addition of a selective precipitation agent to precipitate impurity DNA. Although it is stated therein that a nuclease step is not required when that method is used, such a step in a later stage of the procedure is used for robustness. The method according to the present invention, including the step of adding a nuclease prior to host cell lysis, might suitably be combined with the

addition of a selectively precipitation agent after lysis, thereby making a step of nuclease addition later in the process (as preferred in WO 03/097797) potentially superfluous.

5 International patent application WO 02/070673 employs a continuous centrifugation method for isolation of virus from host cells: the cell culture is subjected to continuous centrifugation under conditions effective to concentrate the cells into a pellet, and the pelleted cells are ejected from the centrifuge into a collection receptacle under conditions effective to lyse the cells and thereby obtain a lysate. Clearly, lysing the cells according to that method is also within the scope of 'lysing the host cells' according to the present invention, and hence it is anticipated that also such 10 a method should benefit from the present invention, i.e. addition of nuclease to the cell culture before subjecting it to the continuous centrifugation method, the thus improved method resulting in lower nucleic acid contamination in the lysate and hence in the final purified product.

15

20

Clarification

In preferred embodiments of the invention, the host cell lysate comprising the virus is clarified. Clarification may be done by a filtration step, removing cell debris and other 25 impurities. Suitable filters may utilize cellulose filters, regenerated cellulose fibers, cellulose fibers combined with inorganic filter aids (e.g. diatomaceous earth, perlite, fumed silica), cellulose filters combined with inorganic filter aids and organic resins, or any combination thereof, and polymeric 30 filters (examples include but are not limited to nylon, polypropylene, polyethersulfone) to achieve effective removal and acceptable recoveries. In general, a multiple stage

process is preferable but not required. An exemplary two or three-stage process would consist of a coarse filter(s) to remove large precipitate and cell debris followed by polishing second stage filter(s) with nominal pore sizes greater than 5 0.2 micron but less than 1 micron. The optimal combination may be a function of the precipitate size distribution as well as other variables. In addition, single stage operations employing a relatively tight filter or centrifugation may also be used for clarification. More generally, any clarification 10 approach including dead-end filtration, microfiltration, centrifugation, or body feed of filter aids (e.g. diatomaceous earth) in combination with dead-end or depth filtration, which provides a filtrate of suitable clarity to not foul the membrane and/or resins in the subsequent steps, will be 15 acceptable to use in the clarification step of the present invention.

In one embodiment, depth filtration and membrane filtration is used. Commercially available products useful in this regard are for instance mentioned in WO 03/097797, p. 20-21. Membranes that can be used may be composed of different 20 materials, may differ in pore size, and may be used in combinations. They can be commercially obtained from several vendors.

It has now been found by the present inventors that certain 25 membranes unexpectedly give superior results in the process of the invention, providing much improved clarification compared to other membranes (see example 4).

It is therefore a preferred embodiment of the invention to use a combination of 0.8 μm and 0.45 μm filters, preferably 30 Sartopore-2 filters, for clarification.

Ultrafiltration/diafiltration

In certain embodiments of the invention, the virus suspension is subjected to ultrafiltration/diafiltration at least once during the process, e.g. for concentrating the virus and/or buffer exchange, and/or for concentration and diafiltration of 5 the clarified harvest. The process used to concentrate the virus according to the method of the present invention can include any filtration process (e.g., ultrafiltration (UF)) where the concentration of virus is increased by forcing diluent to be passed through a filter in such a manner that 10 the diluent is removed from the virus preparation whereas the virus is unable to pass through the filter and thereby remains, in concentrated form, in the virus preparation. UF is described in detail in, e.g., Microfiltration and Ultrafiltration: Principles and Applications, L. Zeman and A. 15 Zydney (Marcel Dekker, Inc., New York, NY, 1996). A preferred filtration process is Tangential Flow Filtration ("TFF") as described in, e.g., MILLIPORE catalogue entitled "Pharmaceutical Process Filtration Catalogue" pp. 177-202 (Bedford, Massachusetts, 1995/96). TFF is widely used in the 20 bioprocessing industry for cell harvesting, clarification, and concentration of products including viruses. The system is composed of three distinct process streams: the feed solution, the permeate and the retentate. Depending on application, filters with different pore sizes may be used. In one 25 embodiment of the present invention the retentate is the product, and can be used for further purification steps if desired. For this embodiment, the particular ultrafiltration membrane selected will have a pore size sufficiently small to retain virus but large enough to effectively clear impurities. 30 Depending on the manufacturer and membrane type, for adenovirus nominal molecular weight cutoffs (NMWC) between 100 and 1000 kDa may be appropriate, for instance membranes with

300 kDa or 500 kDa NMWC. The membrane composition may be, but is not limited to, regenerated cellulose, polyethersulfone, polysulfone, or derivatives thereof. The membranes can be flat sheets or hollow fibers. UF is generally referred to

5 filtration using filters with a pore size of smaller than 0.1 μm . Products are generally retained, while volume is reduced through permeation. The two most widely used geometries for TFF in the biopharmaceutical industry are plate & frame and hollow fiber modules. Hollow fiber units for ultrafiltration

10 and microfiltration were developed by Amicon and Ramicon in the early 1970s (Cheryan, M. Ultrafiltration Handbook), even though now there are multiple vendors including Spectrum and A/G Technology. The hollow fiber modules consist of an array of self-supporting fibers with a dense skin layer that give

15 the membranes its permselectivity. Fiber diameters range from 0.5 mm - 3 mm. An advantage of hollow fiber modules is the availability of filters from small membrane areas (ca. 16 cm^2) to very large membrane areas (ca. 28 m^2) allowing linear and simple scale-up. In certain preferred embodiments according to

20 the invention, hollow fibers are used for TFF. These are reported to give less shear and a better viral particle/infectious unit (VP/IU) ratio than flat screen membranes. In certain embodiments, hollow fibers of 0.05 μm are used according to the invention.

25 Diafiltration (DF), or buffer exchange, using ultrafilters is an ideal way for removal and exchange of salts, sugars, non-aqueous solvents separation of free from bound species, removal of material of low molecular weight, or rapid change of ionic and/or pH environments. Microsolute are removed most

30 efficiently by adding solvent to the solution being ultrafiltered at a rate equal to the UF rate. This washes microspecies from the solution at a constant volume, purifying

the retained virus. The present invention utilizes a DF step to exchange the buffer of the lysate prior to further chromatography or other purification steps. According to one embodiment of the invention DF by TFF is performed for buffer exchange, wherein the addition of buffer equals the removal of 5 permeate.

UF/DF can be used to concentrate and/or buffer exchange the virus suspensions according to the present invention in different stadia of the purification process, e.g. the lysate 10 and/or further purified virus suspensions such as those that have undergone chromatography.

In one embodiment according to the invention, the lysate is concentrated by UF/DF 5-fold, and the resulting concentrated virus suspension is buffer exchanged with 6 diafiltration 15 volumes (DFV) of a buffer comprising 1 M NaCl, using a constant volume diafiltration method. It was found that this high salt concentration significantly improves the quality of the resulting virus, as many undesired proteins were lost during this step (see example 2). It is therefore a preferred 20 embodiment according to the invention that the clarified lysate is exchanged against a solution comprising 0.8-2.0 M NaCl, e.g. around 1 M NaCl, or another salt providing an equivalent ionic strength. It will be clear to the person skilled in the art that both the anion and the cation of the 25 salt can be changed.

Before the virus suspension is subjected to anion exchange chromatography, it may be buffer exchanged with a buffer comprising 0.4 M NaCl, or another salt providing an equivalent 30 ionic strength. In one embodiment, this is accomplished by constant volume diafiltration, using 4 DFVs of the desired buffer.

Further purification

According to preferred embodiments of the present invention, the virus suspension that has been obtained by the method according to the present invention, preferably after 5 clarification of the lysate, is further purified, e.g. by methods generally known to the person skilled in the art. This may for instance be achieved by density gradient centrifugation, as for instance discussed in WO 98/22588, p. 59-61.

10 Preferably however, further purification employs at least one chromatography step, as for instance discussed in WO 98/22588, p. 61-70. Many processes have been described for the further purification of viruses, wherein chromatography steps are included in the process. The person skilled in the art will be 15 aware of these processes, and can vary the exact way of employing chromatographic steps to optimize the process of the invention.

It is for instance possible to purify certain viruses by a combination of anion exchange and cation exchange 20 chromatography steps, see US patent 6,008,036.

It is also possible to employ a hydroxyapatite medium for purifying adenovirus, see WO 02/44348.

A reversed-phase adsorption step might also be used, as for instance described in WO 03/097797, p. 26.

25 For adenovirus purification, it is preferred to use at least one anion exchange chromatography step. After the anion exchange chromatography step, the virus may be sufficiently pure. In certain embodiments however a size exclusion 30 chromatography step is further performed to increase the robustness of the process. This step may be prior to or after the anion exchange chromatography step. Obviously, other

purification steps may also be suitably combined with an anion exchange chromatography step.

The use of anion exchange chromatography for adenovirus purification has been extensively described, and this aspect 5 is therefore well within the reach of the person skilled in the art. Many different chromatography matrices have been employed for purification of adenovirus and are suitable, and the person skilled in the art can easily find the optimal anion exchange material for purifying the virus, for instance 10 guided by the following art.

US patent 5,837,520 (see also Huyghe et al., 1995, Human Gene Therapy 6: 1403-1416) describes a method of purifying adenovirus wherein the host cell lysate is treated with a nuclease, followed by anion exchange and metal ion affinity 15 chromatography.

US patent 6,485,958 describes the use of strong anion exchange chromatography for purification of recombinant adenovirus. Anion exchange chromatography has been employed with fluidized bed columns for the purification of adenovirus particles, see 20 WO 00/50573.

Further, expanded bed anion exchange chromatography, and certain chromatographic resins for anion exchange chromatography for purification of adenovirus particles have been described in US patent 6,586,226.

25 In addition to anion exchange columns, anion exchange membrane chromatography products such as those produced by Pall (e.g. Mustang™ series) and Sartorius (e.g. Sartobind series) are suitable. For use of these filters and their advantages in adenovirus purification see for instance WO 03/078592.

30 Clearly, employment of such filters also falls within the scope of the term 'anion exchange chromatography' as used herein.

US patent 6,537,793 describes the purification of adenoviral particles from host cells using ion-exchange chromatography, in particular teaching a preference for Q Sepharose XL types of chromatographic support for this purpose. In one embodiment 5 of the present invention, an adenovirus is further purified using a Q Sepharose XL column.

As described above, the process may further suitably employ a size exclusion chromatography step.

10 International application WO 97/08298 describes the purification of adenoviruses using certain chromatographic matrices to prevent damage to the viruses, including anion exchange and size exclusion steps.

15 US patent 6,261,823 describes a method for purifying adenovirus wherein the adenovirus preparation is subjected to anion exchange chromatography followed by size exclusion chromatography. In the size exclusion step, a group separation of viral particles from impurities of low molecular weight is achieved. According to certain embodiments of the present 20 invention, about 15-30%, preferably about 20% of the column volume is loaded on the size exclusion column (group separation mode of size exclusion chromatography).

Hence, in a preferred embodiment of the invention, an adenovirus suspension that has been prepared according to the 25 method of the invention is further purified using an anion exchange chromatography step and a size exclusion chromatography step.

Buffers

30 Many buffers can be used during purification of the virus according to the present invention. In several embodiments of the present invention, buffers used for UF/DF and anion

exchange chromatography in general contained 0.4-1.0 M NaCl/50 mM TRIS pH 7.5, wherein the concentrations of NaCl were dependent on the process step. In certain preferred embodiments, the buffers used after clarification are free of 5 detergent, magnesium chloride and sucrose. The absence of these additives distinguishes these buffers from those used in known established protocols. Nevertheless, when the methods according to the present invention are employed, a purified and substantially non-aggregated adenovirus is obtained. An 10 advantage of the use of buffers without these additives is that they are easier to prepare, cheaper, and that there is no need to test for removal of the additives.

In one embodiment according to the invention, the adenovirus is buffer exchanged during group separation to -and finally 15 stored in- the buffer that is also used for the Adenovirus World Standard (Hoganson et al, Development of a stable adenoviral vector formulation, Bioprocessing March 2002, p. 43-48): 20 mM Tris pH 8, 25 mM NaCl, 2.5% glycerol.

Obviously, many other buffers can be used, and several 20 examples of suitable formulations for the storage and pharmaceutical administration of purified (adeno)virus preparations can for instance be found in European patent no. 0853660, and in international patent applications WO 99/41416, WO 99/12568, WO 00/29024, WO 01/66137, WO 03/049763.

25

Vectors with specific inserts

In the art, the transgene itself is generally regarded as irrelevant for the purification process. However, as shown herein, the transgene may in specific cases by its expression 30 in the host cell or in the virus influence properties of the virus or may have an influence on the process of purifying the virus.

One such, non-limiting, specific case as found by the present inventors, is where the transgene is the Ebolavirus nucleoprotein. Purifying an adenoviral vector containing the Ebolavirus nucleoprotein gene with the standard purification 5 procedure results in co-purifying the expressed Ebolavirus nucleoprotein. No co-purification of several other transgene expressed proteins was observed (for instance not with Ebola glycoprotein dTM (Sudan), Ebola Glycoprotein dTM (Zaire), measles haemagglutinin protein (MV-H)). This suggests a 10 specific interaction between the Ebola nucleoprotein and Adenovirus, which seems to depend on the characteristics of the Ebola nucleoprotein. Other nucleic acid binding proteins are expected to have similar characteristics and are expected to have an interaction with Adenovirus resulting in co- 15 purification as well. For adenoviruses having such transgenes, including nucleic acid binding proteins, such as nucleoproteins, such as Ebolavirus nucleoprotein, it is beneficial to exchange the buffer to salt concentrations that are even higher than 1 M NaCl, and use for instance 2-5 M NaCl 20 buffers to improve the final product quality (see example 3). Buffer exchange may suitably be performed by TFF. Alternatively, other methods for buffer exchange could be used, for instance the salt could be added to the virus 25 suspension directly in a gradual way by addition of the solid material or concentration solution. This aspect of the invention may be beneficially combined with other aspects of the invention, for instance with adding the nuclease before lysis, but is not limited thereto. It is described herein that use of such high salt buffers unexpectedly does not result in 30 aggregation problems, nor in significant deterioration of the infectivity or integrity of the purified viral particles. In this aspect of the invention, the buffer exchange step

preferably takes place after the elution of the virus from anion exchange chromatography, and preferably before a further purification step. Such a further purification step may for instance be a size exclusion step in group separation mode.

5 This last step can be used for polishing the virus suspension, i.e. removing minor impurities that may still be present after anion exchange, but also for buffer exchange directly on the group separation column. Alternatively, instead of size exclusion, the further purification step may comprise a

10 filtration of the virus suspension comprising the high salt concentration through a hydrophilic filter, such as a Durapore PVDF filter (e.g. Millipac from Millipore) or a Sartopore 2 filter. The filter preferably has a pore size of 1.2 μm , more preferably smaller, e.g. 1.0 μm , still more preferably

15 smaller, e.g. 0.8 μm , 0.45 μm or 0.22 μm . Unexpectedly, the nucleoprotein (NP) of Ebolavirus was found to be separated from a recombinant adenovirus under these conditions by being retained by the filter, while NP -having a molecular weight of about 100 kD- was expected to pass through the filter pores

20 together with the adenovirus. Use of these filters provides a fast solution for separating the nucleoprotein from the virus, as no prolonged incubation in high salt is required for this procedure, while it allowed complete removal of the nucleoprotein from the virus (Fig. 9). Of course, a size

25 exclusion chromatography step may still be employed after such a filtration step, to remove other minor contaminants and/or for buffer exchange.

30 Use of high salt for removing DNA binding proteins is an aspect of the invention that is expected to be useful for other viruses than adenoviruses as well. Possibly another column chromatography step may in that case be applied instead of anion exchange chromatography. The important factor seems

to be the removal of sufficient contaminating material before the high salt step is applied, and of course this removal could be achieved by other means than anion exchange chromatography, also for recombinant adenoviruses.

5 Hence the invention further provides a method for the production of a virus comprising a nucleic acid sequence coding for a nucleic acid binding protein, comprising the steps of: a) culturing host cells that have been infected with virus, b) subjecting said culture of host cells and said virus 10 therein produced to lysis of the host cells to provide a lysate comprising said virus, c) subjecting the virus to anion exchange chromatography, characterized in that after anion exchange chromatography the virus containing mixture is buffer exchanged with a solution comprising at least 1 M NaCl, or 15 another salt providing an equivalent ionic strength. Preferably, the virus is further purified using at least one step comprising either filtration though a hydrophilic filter, and/or using at least one step comprising size exclusion chromatography. For these embodiments, a solution comprising 20 at least 1 M NaCl or another salt providing equivalent ionic strength is referred to as a 'high salt' solution. Clearly, both the anion and the cation can be varied as is known to the person skilled in the art, as long as sufficient ionic strength is provided without precipitation or other undesired 25 side-effects such as inactivation of the virus, as the method likely depends on the breaking of ionic interactions between the DNA binding protein and the purified virus. For example, NaCl may be in part or wholly substituted for other salts, such as for instance KCl, sodium phosphate, CsCl, LiCl, 30 (NH₄)₂SO₄, NH₄Cl, NaBr, NaI, KBr, KI, KNO₃, NaHCO₃, KHSO₄, etc. A 5x dilution of the buffer used in the example of the invention (comprising 5 M NaCl) had a conductivity of 78-79 mS/cm.

Buffers containing other salts, and having a similar or higher conductivity can for instance now easily be tested for suitability in removing DNA binding proteins from partially purified virus, according to the invention. It is expected 5 that this embodiment will work up to saturation of the NaCl concentration (this is about 6 M NaCl), but for practical reasons it is preferred to use buffers that are not saturated, e.g. 5 M NaCl. Preferably, the solution comprises at least 1.5 M NaCl, or another salt providing an equivalent ionic strength. More preferably the solution comprises at least 2 M NaCl, or another salt providing an equivalent ionic strength. More 10 preferably, the solution comprises at least 3 M NaCl, or another salt providing an equivalent ionic strength. More preferably, the solution comprises at least 4 M NaCl, or another salt providing an equivalent ionic strength. Even more 15 preferably, the solution comprises around 5 M NaCl, or another salt providing an equivalent ionic strength. The high salt solution comprising the virus may be incubated for a certain time, preferably at least one hour, more preferably at least 20 two hours. In general, the examples show an increased purification of the DNA binding protein from the virus when incubation is longer, at least up to overnight. Further, a higher ionic strength appears to improve the purification. Hence, it is conceivable that even at ionic strengths of 1 M 25 or 1.5 M NaCl and prolonged incubation, e.g. for at least two days, or one week, there may be purification of the DNA binding protein from the virus. This can be routinely checked by the experiments described herein. Overnight incubation of recombinant adenovirus expressing Ebolavirus nucleoprotein in 30 a buffer comprising 5 M NaCl, removed the contaminating nucleoprotein from the virus to below detection limits, and is therefore a preferred embodiment of the invention. In

preferred embodiments, the virus is a recombinant adenovirus. In certain embodiments, said nucleic acid binding protein is a nucleoprotein of a virus. In certain embodiments thereof the nucleic acid binding protein is the Ebolavirus nucleoprotein.

5 In preferred embodiments, the buffer exchange step takes place after anion exchange chromatography and before a filtration and/or size exclusion chromatography step. It is further preferred to include a nuclease treatment of the lysate, whereby preferably the nuclease is added to the cell culture

10 before lysis is complete, in accordance with other aspects of the invention. Instead of high salt or in addition thereto, detergent may be added to purify the virus from contaminating DNA binding protein. In one experiment, the inventors have shown that addition of 1% Tween 20 also significantly reduced

15 the contaminating nucleoprotein from recombinant adenovirus expressing Ebola nucleoprotein. Of course, other detergents can suitably be tested, and the concentration may be varied, e.g. between about 0.2% and 5%, to find optimal conditions for removal of DNA binding proteins from recombinant virus

20 preparations according to the invention. In this aspect, preferably at least 1% detergent is added. The first experiments of the inventors however have indicated a higher reproducibility of high salt incubation for this purpose, and therefore this is preferred.

25

Batches of recombinant adenovirus

In one aspect, the invention provides a batch of recombinant adenovirus comprising a transgene chosen from the group consisting of: an Ebolavirus nucleoprotein, an

30 Ebolavirus glycoprotein, a *Plasmodium falciparum* circumsporozoite gene, measles virus hemagglutinin, said batch characterized in that it contains less than 0.1 ng host cell

DNA per 1E11 viral particles. Of course, these transgenes optionally may contain deletions, additions, and/or mutations compared to the wild-type sequences found in nature, including all isolates or subtypes, without deviating from the scope of 5 this aspect of the invention. Clearly, for administration to subjects it is advantageous, if not already required for regulatory purposes, to have batches with such low amounts of contaminating host cell DNA available. In preferred aspects, the batch is characterized in that it contains less than 0.08 10 ng, more preferably less than 0.06 ng, still more preferably less than 0.04 ng host cell DNA per 10¹¹ viral particles.

EXAMPLES

The following examples are included to further illustrate the 15 invention by means of certain embodiments of the invention, and are not to be construed to limit the scope of the present invention in any way.

Example 1. Addition of nuclease to the cell culture instead of 20 to the host cell lysate improves the process for virus purification.

In this example it is shown that addition of nuclease to the cell culture before lysing the cells reduces the amount of residual host cell DNA in the final purified bulk.

25 In runs 1 and 2 a 10 liter PERC.6™ cell culture was lysed with 1% Triton X-100® (Sigma) at day 2.5 after infection with an adenoviral vector. Thirty minutes after lysis, Benzonase® (Merck KgaA, 50 units/ml) and MgCl₂ (2 mM) were added. After another 30 minutes the Triton X-100®/Benzonase® (T/B) harvest 30 was clarified by filtration. This therefore was a run according to processes known in the art.

In runs 3-8, Benzonase® (50 U/ml) and MgCl₂ (2mM) were added to 10 liter PERC.6™ cell culture (day 2.5 post infection), and after 10 minutes incubation the cells were lysed with 1% Triton X-100®. After an additional incubation of 5 50 minutes the Benzonase®/Triton X-100® (B/T) harvest was clarified by filtration.

The difference with the processes known from the art therefore is in the order in which the nuclease (Benzonase®) and the detergent (Triton X-100®) were added: classically first 10 the cells are lysed, and subsequently nuclease is added (referred to herein as T/B harvest), whereas in the process according to the invention, first nuclease is added and subsequently the cells are lysed (referred to herein as B/T harvest). This is schematically shown in Fig. 1.

15 The samples were then further purified. Clarification was performed by depth filtration (0.5 µm Clarigard filter, Millipore) followed by further clarification over a 0.8/0.45 µm Sartopore 2 (Sartorius) filter. The clarified material was concentrated 5 times over a 0.05 µm hollow fiber (Spectrum), 20 followed by diafiltration with subsequently 6 volumes of 1.0 M NaCl/50 mM TRIS pH 7.5 and 4 volumes of 0.4 M NaCl/50 mM Tris pH 7.5. The diafiltered retentate was loaded onto a Sepharose Q-XL (Amersham) column and the virus fraction was eluted with 0.55 M NaCl/50 mM TRIS pH 7.5. This fraction was further 25 purified and buffer exchanged with a Sepharose 4 FF (Amersham) column. The generated purified bulk was concentrated to the desired concentration with a hollow fiber (0.05 µm poresize, Spectrum), 0.22 µm filtered and aliquotted. Purified bulk samples were analysed for residual host cell DNA by Q-PCR.

30 The T/B treatment resulted in a reduction of DNA that after further downstream processing could just meet the

required specification in the filled and finished material. Regulatory requirements for residual host cell DNA for life virus formulations are <10 ng per dose (assumed that a dose contains 1E11 viral particles).

5 As is shown in Table 1, reversing the Triton X-100® and Benzonase® steps reduced the amount of residual host cell DNA in the purified bulk significantly: by the addition of nuclease before active cell lysis the amount of residual host cell DNA could be reduced 10 to 40 times, to less than 0.1 10 ng/1E11 viral particles.

Further, it is clear from SDS-PAGE analysis (Fig. 2) that upon clarification by depth and membrane filtration of a B/T harvest a number of host cell proteins, among which a significant amount of histon proteins (M_w around 10-20 kD on 15 gels, identity confirmed by mass spectrometry), was removed during clarification while these proteins are clearly still present in the clarified T/B harvest.

Hence, the process according to the invention results in significant advantages over those known from the prior art. 20 Without wishing to be bound by theory, possible explanations for the differences between runs 1 and 2 (T/B) on one side and runs 3-8 (B/T) on the other side may include:

1. Upon addition of Benzonase® the DNA released from cells lysed due to virus production can already be digested. As soon 25 as DNA is released from cells lysed by Triton, the Benzonase® is present to immediately digest the DNA, thereby preventing the formation of large DNA aggregates. Digestion of non-aggregated DNA is probably more effective than digestion of major DNA aggregates.

2. The total incubation time of Benzonase® increases with 30 minutes, resulting in more effective digestion (see Benzonase® brochure Merck KGaA code W 214950).

3. Possibly larger histon complexes are formed when the DNA is 5 digested immediately upon release and these larger particles are retained by the clarification filters. Retainment of histon-DNA complexes during clarification might also have contributed to reduction of residual host cell DNA.

Several anion exchange resins have been tested e.g. QAE 10 550C and Super Q 650M (purchased from Tosoh), Q Sepharose HP, ANX Sepharose 4FF, DEAE Sepharose, Q Sepharose XL, Q Sepharose Big Bead and Q Sepharose FF (purchased from Amersham). Although all these resins were suitable for the purification 15 of the recombinant adenoviruses, we found that Q Sepharose XL was best suitable for our purpose based on separation of virus from host cell proteins and host cell DNA, and flow characteristics.

Several size exclusion resins were tested e.g. Sephacryl S300, Sephacryl S500 Sepharose 4FF and Sepharose 6 FF (all 20 purchased from Amersham). Although all these resins were suitable for the purification of the recombinant adenoviruses, we found Sepharose 4 FF best suitable for our purpose based on ability to separate virus from host cell proteins and DNA.

Based upon these and other results (see below), a 25 preferred process according to the invention is shown schematically in Fig. 4.

Example 2. Buffer exchange with high salt buffer improves virus process.

30 PERC.6™ cells were grown in a 10 L bioreactor and infected with Ad5.Adapt.MV-H (with measles virus hemagglutinin as transgene, described in international patent application

PCT/EP03/50748). 2.5 days after infection the cells were lysed with 1% Triton® X-100, after 30 minutes Benzonase® (50 units/ml) and MgCl₂ were added and incubated for another 30 minutes. The harvest was clarified over a 0.5 µm Clarigard 5 filter and subsequently by a Millistak DE 30/60 filter (Millipore). The clarified harvest was diluted with an equal volume of 0.6 M NaCl/50 mM HEPES pH 7.5, resulting in a final concentration of 0.3 M NaCl. The diluted clarified harvest was concentrated 4 times with a 500 kD flatscreen cassette (Biomax 10 500, Pellicon 2 module Millipore) and subsequently diafiltered with 2 diafiltration volumes (DFV) of 0.3 M NaCl/50 mM HEPES pH 7.5; 2 DFV of 0.6 M NaCl/50 mM HEPES pH 7.5; 2 DFV of 1.0 M NaCl/50 mM HEPES pH 7.5; and 3 DFV of 0.3 M NaCl/50 mM HEPES pH 7.5. The conductivity of the generated permeates was 15 measured and the samples were analysed by SDS-PAGE (Fig. 3). The data showed that histones (M_w around 10–20 kD on gels, identity confirmed by mass spectrometry) are passing the membrane pores when the salt concentration of the permeate (and therefore of the retentate) is in the range of 0.55 and 20 0.85 M NaCl, or higher.

A possible explanation is that an electrostatic interaction is broken under these salt conditions resulting in release of histones from complexes allowing passage through 500 kD pores. From this experiment it is concluded that introduction of a 25 high salt buffer during the UF/DF step results in more efficient removal of host cell proteins, especially histon proteins.

Although in this example the cells were lysed first and subsequently treated with nuclease (T/B), it is anticipated that the diafiltration against buffer with high salt strength 30 (higher than 0.55 M NaCl, for instance 1 M NaCl) is also beneficial in the process according to the invention wherein

the nuclease is added to the cells before they are lysed (B/T, see example 1), even though in the B/T process there is already less histon contamination (see Fig. 2).

Therefore, in a preferred embodiment of the process according 5 to the invention, the clarified lysate is exchanged against a solution comprising 0.8-2.0 M NaCl, preferably about 1 M NaCl, or another salt providing an equivalent ionic strength (see example 1 and Fig. 4).

10 *Example 3. Removal of contaminating nucleoprotein from recombinant virus preparations*

Generation of recombinant adenovirus with Ebola nucleoprotein as a transgene is described in example 5. In this example, the purification of such virus is described.

15 Experiment 3.1

Ad5dE3x.Adapt.Ebo.NP was purified with the described protocol (see example 1, Fig. 4). This method resulted in co-purification of the expressed Ebola nucleoprotein (NP) transgene with the virus. Filled and finished product was 20 diluted 1:2 with a buffer containing either 5 M NaCl (final conc 2.5 M), or 2% Tween 20 (final conc 1%) and incubated for 1 hr at room temperature before loading onto a Sepharose 4 FF column. The void and retarded fractions were analysed by SDS-PAGE. The results (Fig. 5) show that the void fraction 25 contained Adenovirus type 5 without contaminating intact NP. Thus far, the results with the high salt appeared reproducible, whereas those with the detergent were not, and hence high salt is preferred. Optimal conditions for detergent however can be tested by varying the detergent used and its 30 concentration.

Conclusion: The Ad5dE3x.Adapt.Ebo.NP vector can be purified from the Ebola nucleoprotein by incubation in a buffer

containing either 2.5 M NaCl or 1% Tween, preferably 2.5 M NaCl, followed by separation on 4 FF sepharose.

Experiment 3.2

5 Ad5dE3x.Adapt.Ebo.NP was purified with the described protocol (see example 1, Fig. 4). Filled and finished product was dialysed with a 10 kD membrane against a 50 mM TRIS buffer pH 7.5 containing 1, 2, 3 or 5 M NaCl. The Ad5.Ebo.NP was incubated in these buffers for 2 hours or overnight before 10 loading onto a Sepharose 4 FF column. The void and retarded fractions were analysed by SDS-PAGE. The results show that the void fraction contained Adenovirus type 5 with significantly less NP. As shown in Table 2, the amount of removal of NP relates to the saltconcentration and incubation time.

15 Conclusion: The Ad5dE3x.Adapt.Ebo.NP vector can be purified from the Ebola nucleoprotein by incubation in a buffer containing either 2-5 M NaCl followed by separation on 4 FF sepharose. A longer incubation time and a higher salt concentration before separation on the 4 FF column results in 20 higher purity of the Ad5.Ebo.NP vector (more removal of nucleoprotein).

Concentrations of 1 M and 1.5 M NaCl are tested with longer 25 incubation times (e.g. 2 days, 1 week) according to this same method to find out whether a longer incubation time may suffice for purification at these salt strengths.

Experiment 3.3

The experiment is schematically indicated in Fig. 6.

PERC.6™ cells were grown in a 10 L bioreactor and infected 30 with Ad5.dE3x.Adapt.Ebo.NP. 2.5 days after infection Benzonase® (50 units/ml) and MgCl₂ were added to the cell culture, after 10 minutes the cells were lysed with 1% Triton® X-100, and

incubated for another 50 minutes. The harvest was clarified over a 0.5 μm ClariGuard filter and subsequently by a Sartopore 2 filter (0.8/0.45 μm , Sartorius).

The clarified harvest was split in two portions. One portion was concentrated 5 times and diafiltered against a buffer containing 5 M NaCl/50 mM Tris pH 7.5 by use of a 0.5 μm hollow fiber (Spectrum). This resulted in an increase of trans membrane pressure (TMP) and a reduction in permeate flux while the visual appearance of the retentate turned to white and less transparent, indicating precipitation of proteins.

The second portion of clarified harvest was concentrated 5 times and diafiltrated with 6 DFV of 1.0M NaCl/50 mM TRIS pH 7.5 followed by 4 DFV of 0.4 M NaCl/50 mM TRIS pH 7.5 by use of a 0.5 μm hollow fiber (Spectrum). The final retentate was purified over a Sepharose Q-XL column (Amersham).

The Q-XL eluate was also divided into two portions. One portion was further purified and buffer exchanged to 25 mM NaCl/20 mM TRIS/ 2.5 % glycerol (formulation buffer) over a size exclusion column (Sephadex G-25) in group separation mode (loading of 20% of column volume); this is product A in Fig. 6. The other portion was diafiltrated against 6 DFV of 5 M NaCl/50 mM TRIS pH 7.5 by use of a 0.05 μm hollow fiber (Spectrum): this is further called the high salt virus fraction.

Although the poresizes of the hollow fiber (0.05 μm , about 800 kD) are large enough to allow passage of a 100 kD nucleoprotein, no nucleoprotein could be detected in the permeate and no reduction of the amount of nucleoprotein was seen in the retentate. Possibly, the adaptation of one or more TFF parameters (e.g. increase in shear) may improve purification of the nucleoprotein. We have further used size exclusion (group separation) to achieve this goal.

The high salt virus fraction was again split into two portions: one portion was directly purified and buffer exchanged to formulation buffer over a size exclusion (group separation) column (product B in Fig. 6), while the second 5 fraction was stored overnight at room temperature before further purifying and buffer exchanging over a size exclusion (group separation) column (product C in Fig. 6).

The three purified bulk lots were analysed to determine purity, infectivity, yield, aggregation and transgene 10 expression.

SDS-PAGE and Western analysis is shown in Fig. 7, and shows that the intact nucleoprotein, as well as NP degradation products (confirmed by mass spectrometry to be NP degradation products), are increasingly removed from product A, B and C 15 respectively.

Reverse phase analysis (RP-HPLC) (Fig. 8) shows that the amount of intact nucleoprotein, as well as NP degradation product (eluting at 39 minutes), was reduced by introducing the high salt diafiltration step from about 50% (product A) to <5% 20 (product B) and after overnight storage in 5 M NaCl at room temp even to below the detection limit of 1% (product C). Using both analysis methods, no effect on viral proteins was observed.

Transgene expression was shown, the infectivity was unaffected 25 and no aggregation occurred (for all three products A, B and C). Apparently, the incubation of the recombinant virus in high salt, even overnight, did not lead to a significant reduction in quality of the virus.

Instead of or in addition to prolonged incubation with 30 high salt and subsequent size exclusion, a virus suspension that was buffer exchanged with 5M NaCl was directly filtered using a 0.45 μ m hydrophilic filter (Millipac 20).

Unexpectedly, this resulted in a complete removal of NP from the virus (Fig. 9). This experiment is repeated with filters of different pore sizes (e.g. 1.2, 1.0, 0.8, 0.22 μm) to determine the range of possible pore sizes. A 0.8/0.45 μm 5 Sartopore-2 combination is also tested. This filtration step may suitably be combined with a subsequent size exclusion chromatography step, and may require shorter incubation times of the virus in the high salt solution, resulting in a possible savings in process time.

10 Conclusions: 1. Diafiltration of the clarified harvest to 5 M NaCl is not feasible probably due to precipitation of host cell proteins. 2. Incubation of highly purified Ad5dE3x.Adapt.Ebo.NP in 5 M NaCl followed by separation on Sepharose 4 FF or by filtration through a hydrophilic filter 15 results in purification of Ad5dE3x.Adapt.Ebo.NP from the Ebola nucleoprotein. 3. Prolongation of the incubation step from two hours to overnight results in an even further reduction of residual nucleoprotein from <5% to <1%. Filtration through hydrophilic filters may reduce the required incubation time to 20 obtain the same result.

Hence, it is feasible to remove nucleic acid binding 25 proteins, such as nucleoproteins, e.g. nucleoprotein of Ebolavirus, from recombinant viruses expressing such proteins, by incubation in at least 2M NaCl, preferably at least 3 M NaCl, more preferably 5 M NaCl for purification purposes of batches of such viruses.

Example 4. Testing different filters for clarification.
PERC.6™ cells were grown in a 10 L bioreactor and infected in 30 separate experiments with different recombinant adenoviruses. 2.5 days after infection the cells were lysed with 1% Triton® X-100, after 30 minutes Benzonase® (50 units/ml) and MgCl₂ were

added and incubated for another 30 minutes. The harvest was used for clarification experiments.

5 Depth filters, e.g. Clarigard and Polygard had high recovery (>90%) and good removal of cell debris (microscopic analysis), and were found suitable as an initial clarification filter. However the filtrate still looked opalescent.

10 Millistak DE 30/60 and CE50 were found to be less suitable for filtering T/B harvest due to loss of virus (20-45%). In later fractions the yield increased but the retention of opalescence decreased, indicating that the filter capacity was reached.

15 Several membrane filters were tested to further clarify the filtrate produced by Clarigard filtration; e.g. Milligard 0.5 μm , 1.2 μm and 1.2/0.22 μm , Durapore 0.22 and 0.65 μm , Lifegard 1.0 and 2.0 μm (all Millipore) and Sartopore-2 0.8/0.45 μm (Sartorius). The Sartopore 2 filter was the only filter among those tested that had a good retention of the opalescence, a high capacity (>20 ml/cm²) as well as a high 20 virus yield (>95%).

) The clarified harvest was concentrated and diafiltrated with flatscreen or hollow fiber modules. Several filters were 25 tested to filter the final retentate, preferably with a 0.45 μm poresize, in order to make the final retentate suitable for chromatography, e.g.: Millipack 20, Lifegard 1.0 μm , Polygard 0.6 μm , Intercept Q, Milligard 1.2/0.5 μm . Again the Sartopore 2 filter was the only filter among those tested that had a good retention of the opalescence, a high capacity as well as a high virus yield (>95%).

30 Although these experiments were done with a T/B harvest, later experiments have confirmed the results above for a B/T harvest according to the invention, and hence a Sartopore 2

filter gives very good results with the methods according to the invention.

Hence, for the clarification in the methods according to the invention preferably a combination of 0.8µm and 0.45 µm 5 filters, preferably a Sartopore 2 filter, is used.

Example 5. Generation and purification of different recombinant adenoviruses.

Various recombinant adenoviruses were purified with methods 10 according to the present invention. Such viruses can for instance be generated by homologous recombination in the packaging cells of a left-end part (sometimes referred to as 'adapter-plasmid', useful for easy cloning of the transgene) and a right-end part of the genome according to methods known 15 from the art, such as for instance described in EP 0955373, WO 03/104467 and WO 2004/001032. The viruses can be propagated in packaging cells known from the art, such as for instance 293 20 cells, PER.C6™ cells (exemplified by cells deposited at the ECACC under no. 96022940, see US patent 5,994,128), or PER.E1B55K cells expressing E1B 55K protein from Ad35 (see US patent 6,492,169). Construction of some recombinant adenoviruses that were and are purified according to the 25 methods of the invention is described in this example.

25 Adenovirus with Ebolavirus transgenes

Generation of pAdapt.Ebola NP

The gene encoding the Ebola subtype Zaire nucleoprotein was amplified by polymerase chain reaction using primers; forward 30 6401 5' GCA CCG GTG CCG CCA TGG ATT CTC GTC CTC A 3' (SEQ. ID. NO. 1) and reverse 6401 5' GCG CTA GCT CAC TGA TGA TGT TGC AG 3' (SEQ. ID. NO. 2) in order to introduce restriction endonuclease recognition sites and a consensus sequence for

optimal translation initiation (Kozak M, 1987, At least six nucleotides preceding the AUG initiator codon enhance translation in mammalian cells. *J Mol Biol.* 20: 947-950) for directional cloning in pAdApt™ (see EP 0955373). PCR reactions 5 were performed in a Biometra T1 or T3 thermal cycler using 10 uM of each primer, 0.75 ul miniprep DNA of VRC6401 (see WO 03/028632), 1.5 units *Pwo* DNA polymerase, 5 ul 10x PCR buffer, 0.5 ul 20 mM dNTPs using the following conditions: 1cycle 5' 94°C, 1' 50°C, 4' 72°C, 5 cycles of 1' 94°C, 1' 50°C, 4' 72°C, 20 10 cycles of 1' 94°C, 1' 62°C, 4' 72°C, 1 cycle of 1' 94°C, 1' 62°C, 15 10' 72°C. Subsequently the PCR product of the correct size was digested with *PinA* I (Isoschizomer of *Age* I) and ligated into the pAdApt™ vector digested with *PinA* I and *Hpa* I. After ligating the fragment for 2 hours at roomtemperature, 50% of 20 the mixture was transformed to *E. coli* DH5α T1R cells by heatshock transformation and plated onto LB agar plates supplemented with 50 ug/ml ampicillin. Twenty colonies were picked and grown overnight at 37°C in LB supplemented with ampicillin. Miniprep DNA was extracted using the Qiagen miniprep Spin kit as described by the manufacturer. After 25 restriction enzyme analysis with *Hind* III and *Xba* I a correct clones was selected and further checked by DNA sequence analysis.

25 *Generation of pAdapt.Ebola GP (Z)*

The gene encoding the Ebola subtype Zaire full-length glycoprotein was amplified by PCR using primers Forward 6001 (5' CCC AAG CTT GCC GCC ATG GGC GTT ACA GG 3') (SEQ. ID. NO. 3) and Reverse 6001 (5' GGC TCT AGA TTA CTA AAA GAC AAA TTT GC 3') (SEQ. ID. NO. 4). PCR reactions were performed in a Biometra T1 or T3 thermal cycler using 10 uM of each primer,

100 ng and 25 ng DNA of VRC6001 (see WO 03/028632), 1.5 units *Pwo* DNA polymerase, 5 ul 10x PCR buffer, 0.5 ul 20 mM dNTPs using the following conditions: 1 cycle 5' 94°C, 1' 55°C, 4' 72°C, 5 cycles 1' 94°C, 1' 55°C, 4' 72°C, 20 cycles 1' 94°C, 5 1' 64°C, 4' 72°C, 1 cycle 1' 94°C, 1' 64°C, 10' 72°C. Subsequently the PCR product of the correct size was digested with *Hind* III and *Xba* I and ligated into the likewise digested pAdApt™ vector. After ligating the fragment for 2 hours at roomtemperature, 50% of the mixture was transformed to *E. coli* DH5 α T1R cells by heatshock transformation and plated onto LB agar plates supplemented with 50 ug/ml ampicillin. Colonies were picked and grown overnight at 37°C in LB supplemented with ampicillin. Miniprep DNA was extracted using the Qiagen miniprep Spin kit as described by the manufacturer. After 10 restriction enzyme analysis with *Hind* III and *Xba* I correct clones were selected and further checked by DNA sequence analysis.

15 *Generation of pAdapt.Ebola GPdTM(Z) and pAdapt.Ebola GPdTM(S)*
20 Similarly as described above, codon optimized sequences encoding one of the Ebola subtypes Zaire and Sudan/Gulu glycoprotein with a deletion of the C-terminal 29 amino acids long transmembrane domain (GPdTM(Z), and GPdTM(S), respectively, see also WO 03/028632), were cloned into pAdapt.

25 *Generation of recombinant adenoviruses with Ebolavirus transgenes*

30 The pAdapt plasmids with the different inserts (pAdapt.Ebola NP, pAdapt.Ebola GP (Z), pAdapt.Ebola GPdTM (S), pAdapt.Ebola GPdTM (Z)), were used to form recombinant adenoviruses by homologous recombination with plasmids comprising the

remainder of the adenovirus type 5 genome (plasmid pWE/Ad.AfIII-rITRspΔE3, which is pWE/Ad.AfIII-rITRsp (see EP 0955373) with a deletion of 1878 bp in the E3 region (XbaI region) was used for the right end of the adenovirus genome),
5 according to well known methods such as for instance described in EP 0955373, resulting in viruses named Ad5dE3x.Adapt.Ebo.NP, Ad5dE3x.Adapt.Ebo.GP(Z), Ad5dE3x.Adapt.Ebo.GPdTM(S) and Ad5dE3x.Adapt.Ebo.GPdTM(Z), respectively. Of course, the transgenes can similarly be 10 cloned in adenovirus vectors of different serotypes, such as Ad35, to generate recombinant adenovirus derived from those serotypes (see e.g. WO 00/70071).

Adenoviruses with Plasmodium transgene

15 *Generation of pAdapt.CS.pFalc and pAdapt535.CS.Pfalc*
A codon optimized circumsporozoite (CS) gene of *Plasmodium falciparum* was synthesized and cloned into pCR-script (Stratagene), as described in international patent application PCT/EP03/51019 (clone 02-659, see SEQ. ID. NO. 5 for sequence 20 of insert). The CS gene was cloned into pAdapt and pAdapt535 (see WO 2004/001032) for generation of respectively recombinant Ad5 and recombinant Ad35 vectors. Clone 02-659 and both pAdapt vectors were digested with *Hind* III and *BamH* I and joined by ligation. After ligating the fragment for 2 hours at 25 roomtemperature, 50% of the mixture was transformed to *E. coli* DH5 α T1R cells by heatshock transformation and plated onto LB agar plates supplemented with 50 μ g/ml ampicillin. Colonies were picked and grown overnight at 37°C in LB supplemented with ampicillin. Miniprep DNA was extracted using the Qiagen 30 miniprep Spin kit. After restriction enzyme analysis with *Hind* III and *Xba* I correct clones were selected and further checked by DNA sequence analysis.

Recombinant adenovirus serotype 5 with the *P.falciparum* CS gene was generated as follows (see for instance EP 0955373; also described in international patent application PCT/EP03/51019). pAdapt.CS.Pfalc was digested by PacI restriction enzyme to release the left-end portion of the Ad genome. Plasmid pWE/Ad.AfIII-rITRsp Δ E3 containing the right-end part of the Ad5 genome has a deletion of 1878 bp in the E3 region (XbaI deletion), and was also digested with PacI. The digested constructs were co-transfected into PER.C6TM cells, such as deposited at the ECACC under number 96022940. Upon homologous recombination of the overlapping sequences, recombinant virus named Ad5 Δ E3.CS.Pfalc was formed.

Recombinant adenovirus serotype 35 with the *P.falciparum* CS gene was generated similarly, but now PacI-digested pAdapt535.CS.Pfalc was used for the left-end of the virus genome, and NotI-digested pWE.Ad35.pIX-rITR Δ E3 (see WO 2004/001032) was used for the right-end of the virus genome, and both were transfected into PER-E1B55K producer cells (having E1B-55K sequences derived from Ad35; cells have been described in US patent 6,492,169). Upon homologous recombination of the overlapping sequences, recombinant virus named Ad35 Δ E3.CS.Pfalc was formed. Of course, it would also be possible to change the E4-orf6 protein in the backbone of the Ad35 virus into E4-orf6 of Ad5, to render it possible to propagate such viruses on packaging cells that express the E1B protein of Ad5, such as PER.C6TM or 293 cells (see WO 03/104467).

Ad5 Δ E3.CS.Pfalc and Ad35 Δ E3.CS.Pfalc are purified according to the methods of the present invention.

Several Adenovirus vectors were purified with the described process (example 1, Fig. 4): Ad5dE3x.Adapt.Ebo.GPdTM(Z); Ad5dE3x.Adapt.Ebo.GPdTM(S); Ad5dE3x.Adapt.Ebo.NP and Ad5dE3x.Adapt.Empty on a 2 to 20 L scale. The filled and finished (F&F) products were analysed for purity by reverse phase and SDS-PAGE and found to be purified near homogeneity (except for the presence of the Ebola nucleoprotein in the preparations of the vectors having Ebola nucleoprotein as a transgene). The amount of residual host cell DNA was measured by Q-PCR and was below 100 pg DNA/1E11 VP (as shown in Table 1)

Aggregation was measured by optical density measurements at 320 and 260 nm, and also by disc centrifugation. None of the batches showed aggregation. Potency was shown in all batches by a VP/IU ratio below 10, and transgene expression was shown in A549 cells.

The final yield ranged from 20-50% dependent on the scale: 2L: 24-26% (n=2), 10 L: 30-37% (n=3), 20 L: 46% (n=1).

CLAIMS

1. A method for the purification of a virus from a host cell, said method comprising the steps of:
 - a) culturing host cells that are infected with a virus,
 - b) adding nuclease to the cell culture, and
 - c) lysing said host cells to provide a lysate comprising the virus.
2. A method according to claim 1, said method further comprising:
 - d) clarification of the lysate.
3. A method according to claim 1 or claim 2, said method further comprising:
 - e) further purifying the virus with at least one chromatography step.
4. A method according to any one of claims 1-3, wherein said virus is a recombinant adenovirus.
5. A method according to any one of claims 1-4, wherein the nuclease of step b) is Benzonase.
6. A method according to any one of claims 1-5, wherein step c) of lysing the host cells is performed with a detergent.
7. A method according to claim 6, wherein the detergent is Triton-X100.

8. A method according to any one of claims 2-7, wherein step
d) comprises depth filtration and membrane filtration.
9. A method according to claim 8, wherein the membrane
5 filtration is performed using a combination of 0.8 μ m and
0.45 μ m filters.
10. A method according to any one of claims 3-9, wherein
prior to step e) the clarified lysate is subjected to
ultrafiltration and/or diafiltration.
10
11. A method according to claim 10, wherein the clarified
lysate that is subjected to diafiltration is exchanged
against a solution comprising 0.8-2.0 M NaCl, preferably
15 about 1 M NaCl, or another salt providing an equivalent
ionic strength.
12. A method according to any one of claims 4-11, wherein
step e) comprises anion exchange chromatography.
20
13. A method according to any one of claims 4-12, wherein
step e) comprises size exclusion chromatography.
14. A method according to any one of claims 4-13, wherein
step e) comprises:
25 e,i) anion exchange chromatography, and
e,ii) size exclusion chromatography.
15. A method according to claim 14, wherein the mixture
30 containing the recombinant adenovirus is buffer exchanged
with a solution comprising at least 2 M NaCl, or another
salt providing an equivalent ionic strength, between said

steps of anion exchange chromatography and size exclusion chromatography.

16. A process according to any one of claims 4-15, wherein
5 the buffers used in steps d) and subsequent steps are
free of detergent, magnesiumchloride and sucrose.

17. A method for the purification of a virus that is capable
10 of lysing host cells, said method comprising the steps
of:
a) culturing host cells comprising said virus capable of
lysing host cells,
b) harvesting virus following their release into culture
fluid without addition of an external lysis factor,
15 characterized in that a nuclease is added to the culture
before 95% of the host cells has been lysed.

18. A method for the production of a virus comprising a
nucleic acid sequence coding for a nucleic acid binding
20 protein, comprising the steps of:
a) culturing host cells that have been infected with said
virus,
b) subjecting said culture of host cells comprising said
virus to lysis of the host cells to provide a lysate
25 comprising said virus,
c) subjecting the virus to anion exchange chromatography,
characterized in that after anion exchange chromatography
the virus containing mixture is buffer exchanged with a
solution comprising at least 1 M NaCl, or another salt
30 providing an equivalent ionic strength and/or with a
solution comprising at least 1% of a detergent.

19. A method according to claim 18, wherein the virus containing mixture is buffer exchanged at least once with a solution comprising at least 1 M NaCl, or another salt providing an equivalent ionic strength.

5

20. A method according to claim 18 or claim 19, wherein said virus is a recombinant adenovirus.

10

21. A method according to any one of claims 18-20, wherein said protein that is capable of binding nucleic acid is a nucleoprotein of a virus.

22. A method according to claim 21, wherein said virus is Ebolavirus.

15

23. A method according to any one of claims 19-22, wherein said solution comprises at least 1.5 M NaCl, or another salt providing an equivalent ionic strength.

20

24. A method according to claim 23, wherein said solution comprises at least 2 M NaCl, or another salt providing an equivalent ionic strength.

)

25

25. A method according to claim 24, wherein said solution comprises at least 3 M NaCl, or another salt providing an equivalent ionic strength.

26. A method according to claim 25, wherein said solution comprises about 5 M NaCl, or another salt providing an equivalent ionic strength.

30

27. A method according to any one of claims 18-26, further comprising filtering the virus containing mixture that is buffer exchanged through a hydrophilic filter with a pore size of 1.2 μm or less.

5

28. A method according to claim 27, wherein said pore size is about 0.45 μm or about 0.22 μm .

10

29. A method according to any one of claims 18-28, further comprising subjecting the virus containing mixture that is buffer exchanged to size exclusion chromatography.

15

30. A batch of recombinant adenovirus comprising a transgene chosen from the group consisting of: an Ebolavirus nucleoprotein, an Ebolavirus glycoprotein, a Plasmodium falciparum circumsporozoite gene, and measles virus hemagglutinin, said batch characterized in that it contains less than 0.1 ng host cell DNA per 1E11 viral particles.

20

ABSTRACT

The invention provides a method for the purification of a virus from a host cell, said method comprising the steps of:
a) culturing host cells, b) infecting said host cells with a
5 virus, c) treating the cell culture with nuclease, d) lysing
said host cells to provide a lysate comprising the virus. The
virus is preferably a recombinant adenovirus. The invention
further provides a method for the purification of a
recombinant virus expressing a heterologous protein that is
10 capable of binding nucleic acid, comprising the steps of: a)
culturing host cells, b) infecting said host cells with said
recombinant virus, c) lysing said host cells to provide a
lysate comprising said recombinant virus, d) subjecting the
recombinant virus to anion exchange chromatography and size
15 exclusion chromatography, characterized in that the virus
containing mixture is buffer exchanged at least once with a
solution comprising at least 2 M NaCl, or another salt
providing an equivalent ionic strength.
